Bacterial conjugation

1

Yeast genera

Saccharomyces

Schizosaccharomyces

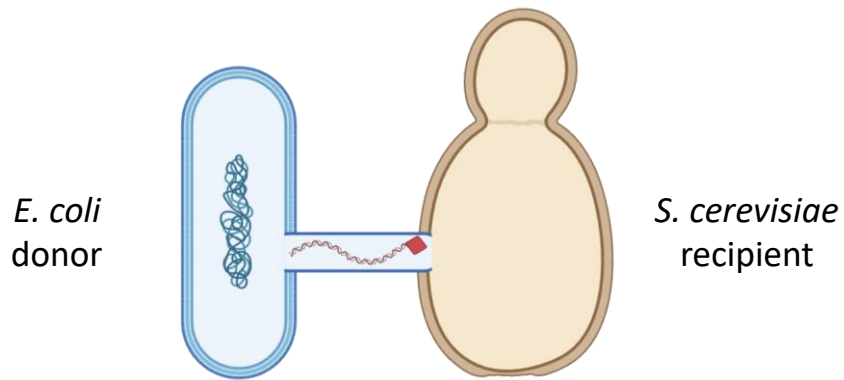

Kluyveromyces

Pichia

Pachysolen

Metschnikowia

Candida

The problem with conjugation:

...it requires cell contact

How do we **increase** or **control** interdomain conjugation (IDC)?

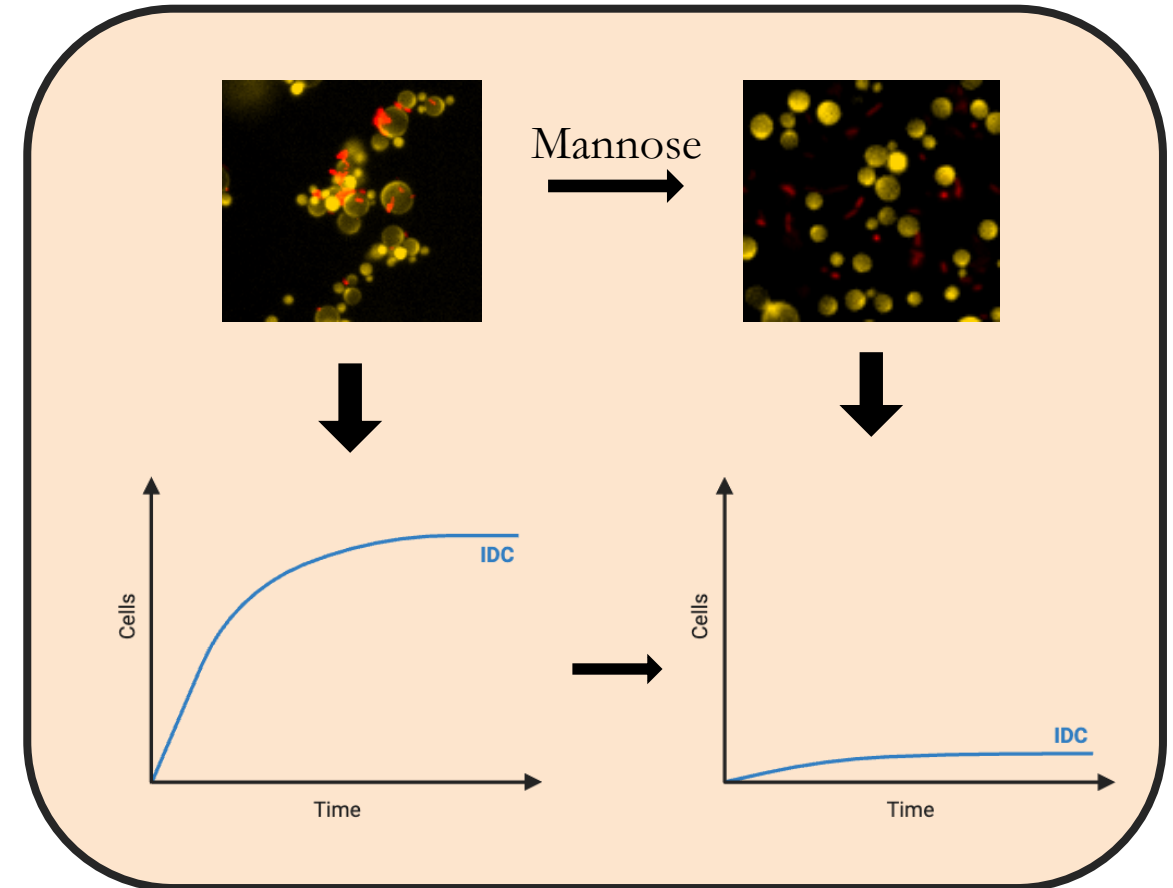

Knobs for control: population ratios and adhesion

Targeted mutations to find optimal growth conditions for IDC

Disruption of cell adhesion to interrupt IDC

Knobs for control: population ratios and adhesion

Targeted mutations to find optimal growth conditions for IDC

The **lower** the long-term donor-to-recipient ratio, the **higher** the net IDC

Disruption of cell adhesion to interrupt IDC

Adherent (clumped) cells result in $\geq 10x$ higher IDC, which can be disrupted

Can we use IDC to rescue a recipient population?

Rescue assay:

Make a sick population healthy by conjugating an essential gene

Unmodified donor
(no tuning)

Mutant donor
(tuned growth)

Can we use IDC to rescue a recipient population?

IDC can rescue a recipient population

IF

we tune populations

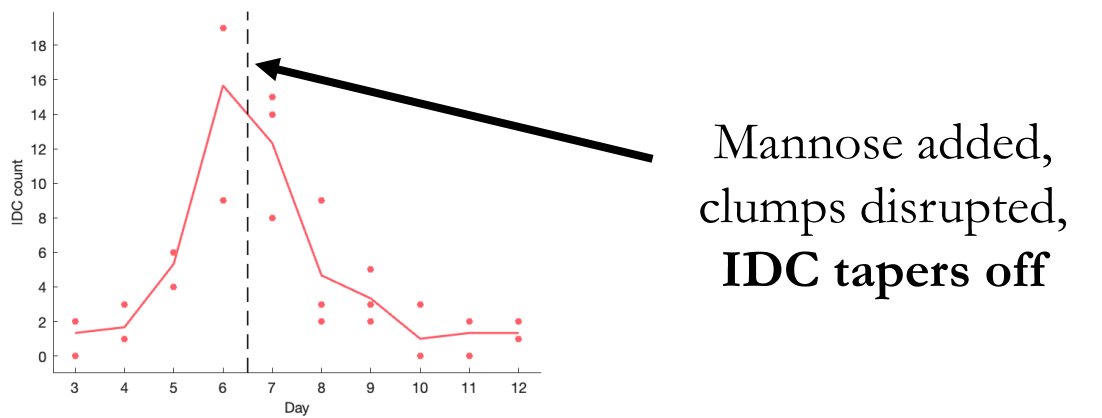

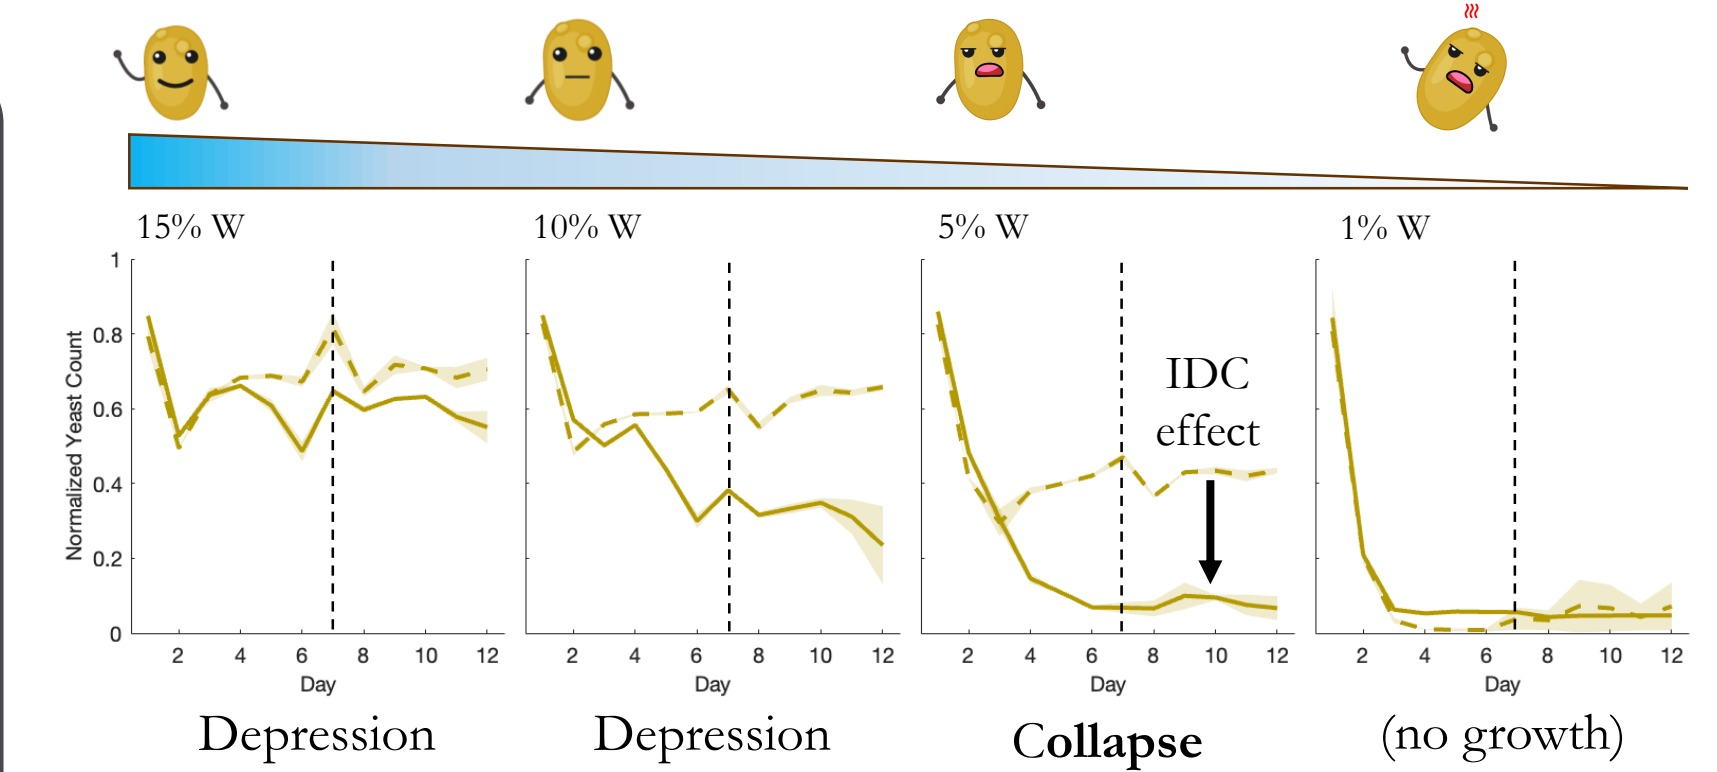

Unmodified donor
(no tuning)

Mutant donor
(tuned growth)

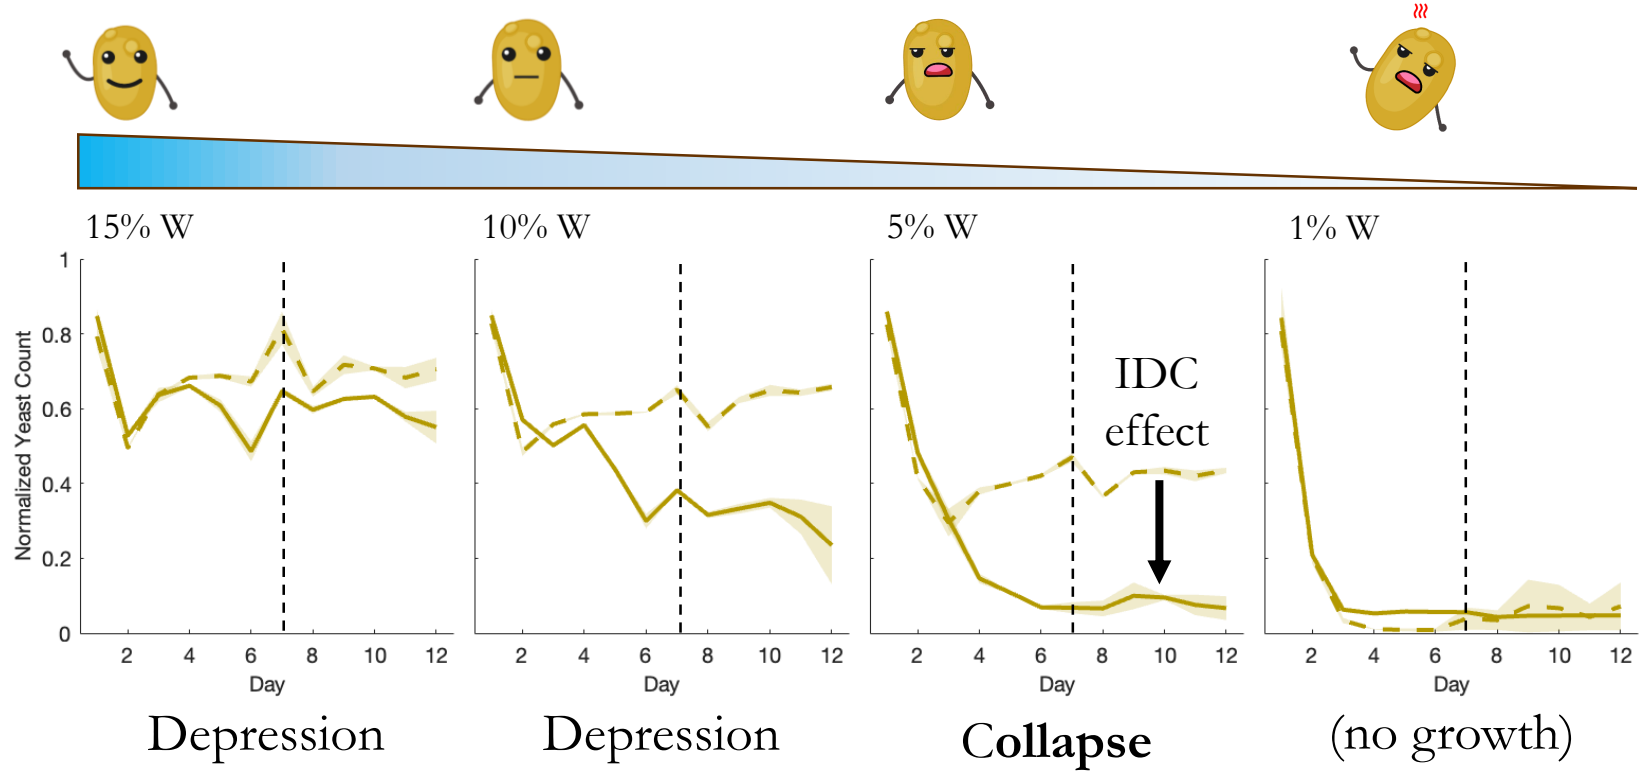

Can we use IDC to kill a recipient population?

Can we use IDC to kill a recipient population?

IDC can depress or collapse recipient populations

We can interrupt IDC function by disrupting cell clumps
